

CNAPP Alert Triage — Design Write-up

Proposed Features

The design helps security engineers move from a large alert queue to the right remediation with minimal investigation and context-switching.

Alert Queue: Prioritized, filterable alerts across cloud accounts with severity, account, provider, and status filters plus summary metrics.

Alert Detail: Explains why an alert was triggered, affected resources, blast radius, compliance impact, and actions such as assign, snooze, or dismiss.

Remediation: Offers manual remediation or one-click fixes for selected low-risk issues, with exception handling and an audit trail.

Prioritization — MoSCoW

Must Have (v1): Filterable alert queue; alert detail with plain-language context; assign/snooze/false-positive actions; basic audit trail.

Should Have (v1.1): Blast-radius context; compliance mapping; manual remediation guidance.

Could Have (v2): One-click remediation for curated low-risk issues; expiring exceptions/allowlists; similar-alert clustering.

Won't Have Yet: Fully autonomous remediation without human approval.

Rationale: The queue and detail view are the foundation of the workflow. Blast radius and compliance context help engineers decide urgency faster. Automation is delayed until trust is established through clear explanations, human approval, and auditability.

Success Metrics

- **Mean Time to Triage:** Reduce by 40%.
- **Mean Time to Resolution:** Reduce time from triage to closure.
- **Critical Alerts Within SLA:** Increase the percentage resolved within the defined SLA.
- **False-Positive Rate:** Maintain or reduce false-positive dismissals.
- **Auto-Remediation Adoption:** Track eligible alerts resolved through one-click remediation in v2.
